

Production Pilot: 3 Modules

FIG. 1

Production Pilot Block Diagram

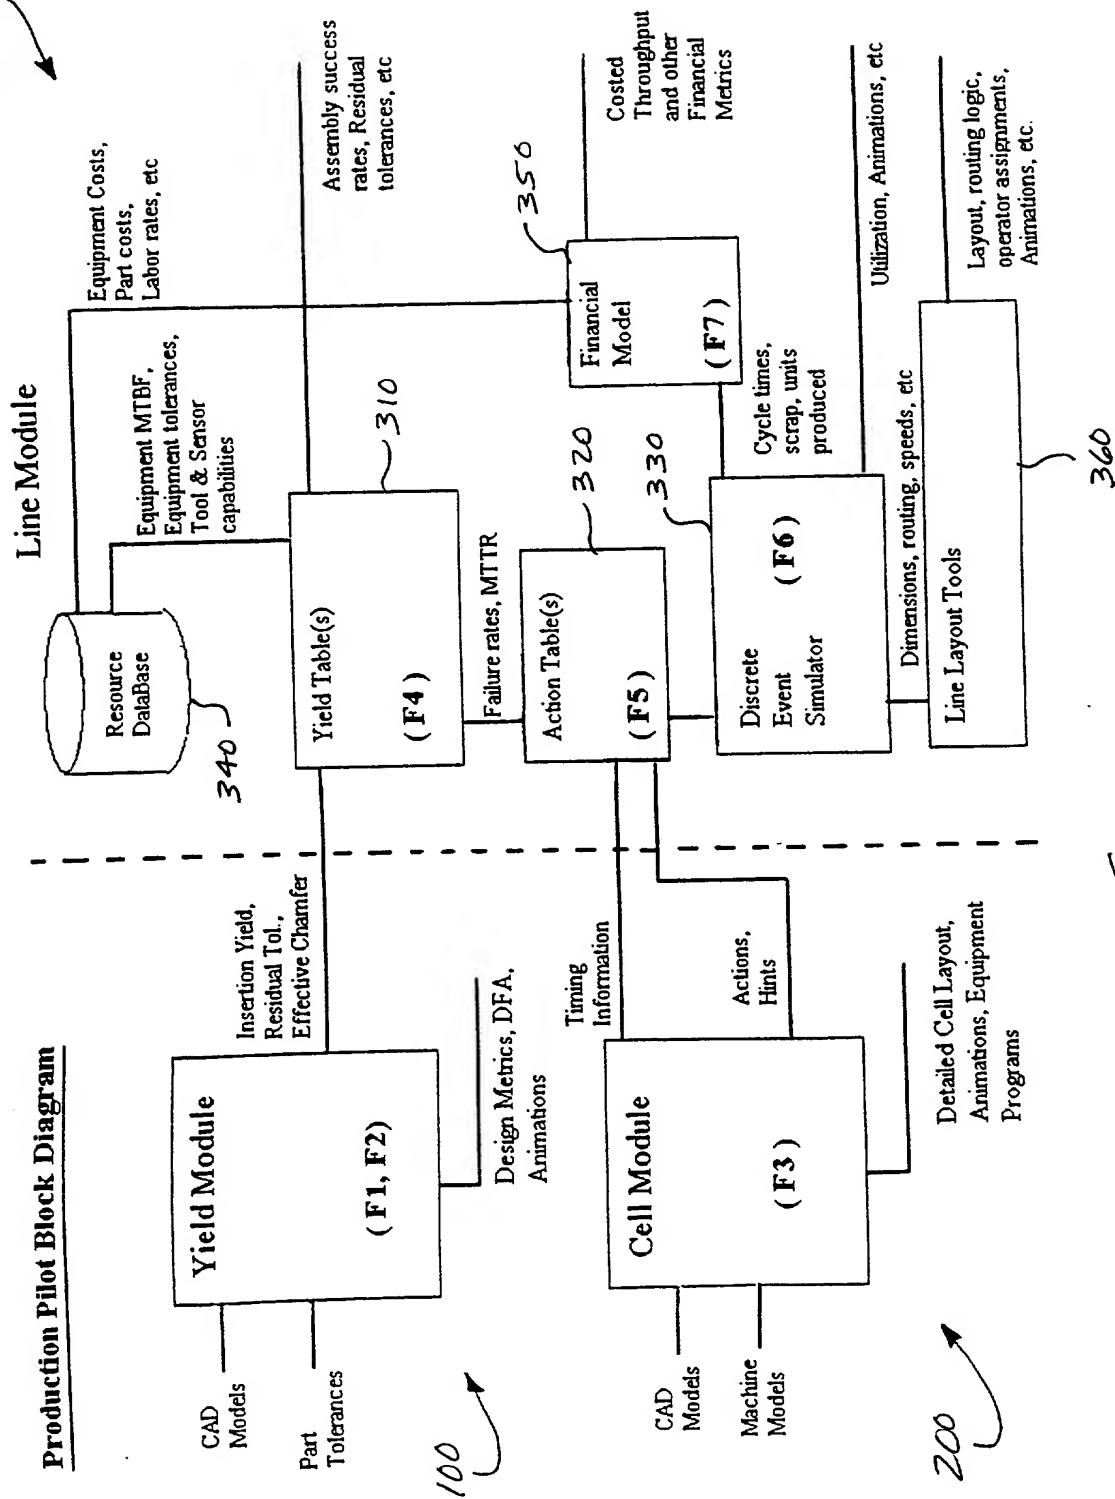

Fig. 2

S1000

START

S1100

Pick "Contact Features" from
CAD models using a Graphical
User Interface

S1200

For each part mate, specify
which Contact Features are
involved.

S1300

Compute the Nominal Mate
Position for the parts, using
the Contact Feature pairs. A1

S1400

Compute Insertion Yield using
the Monte Carlo algorithm
based on the given tolerances. A2

S1500

Compute an estimate of the
Residual Tolerance of the
mate. A3

S1600

Transfer Insertion Yield,
Residual Tolerance, and the
Effective Chamfer to Line.

S1700

S 4000

START

S4100

Transfer new or updated "Actions" from the Action Table in the Line Module. Each of these actions appears as a "comment" line in the detailed automation program in the Cell Module.

S4200

The user adds the detailed programming instructions "in between" the "Action Comments". The original english-like Actions appear to be comments which are then followed by the detailed code that implements those actions.

S4300

When the simulation runs in the Cell Module, the "Action Comments" collect execution times by starting and stopping timers. Thus, the time associated with each of the high-level actions can be recorded.

S4400

Typically Cell Module simulations run in a loop for several iterations. The times collected are stored as a list of durations, also called a "Tabular Distribution". This distribution is transferred to the Line Module and is used directly in the Discrete Event Simulator.
